Day – 4

1. Install FileZilla Server on your Windows machine, create a user account, and set up a shared folder for FTP access.

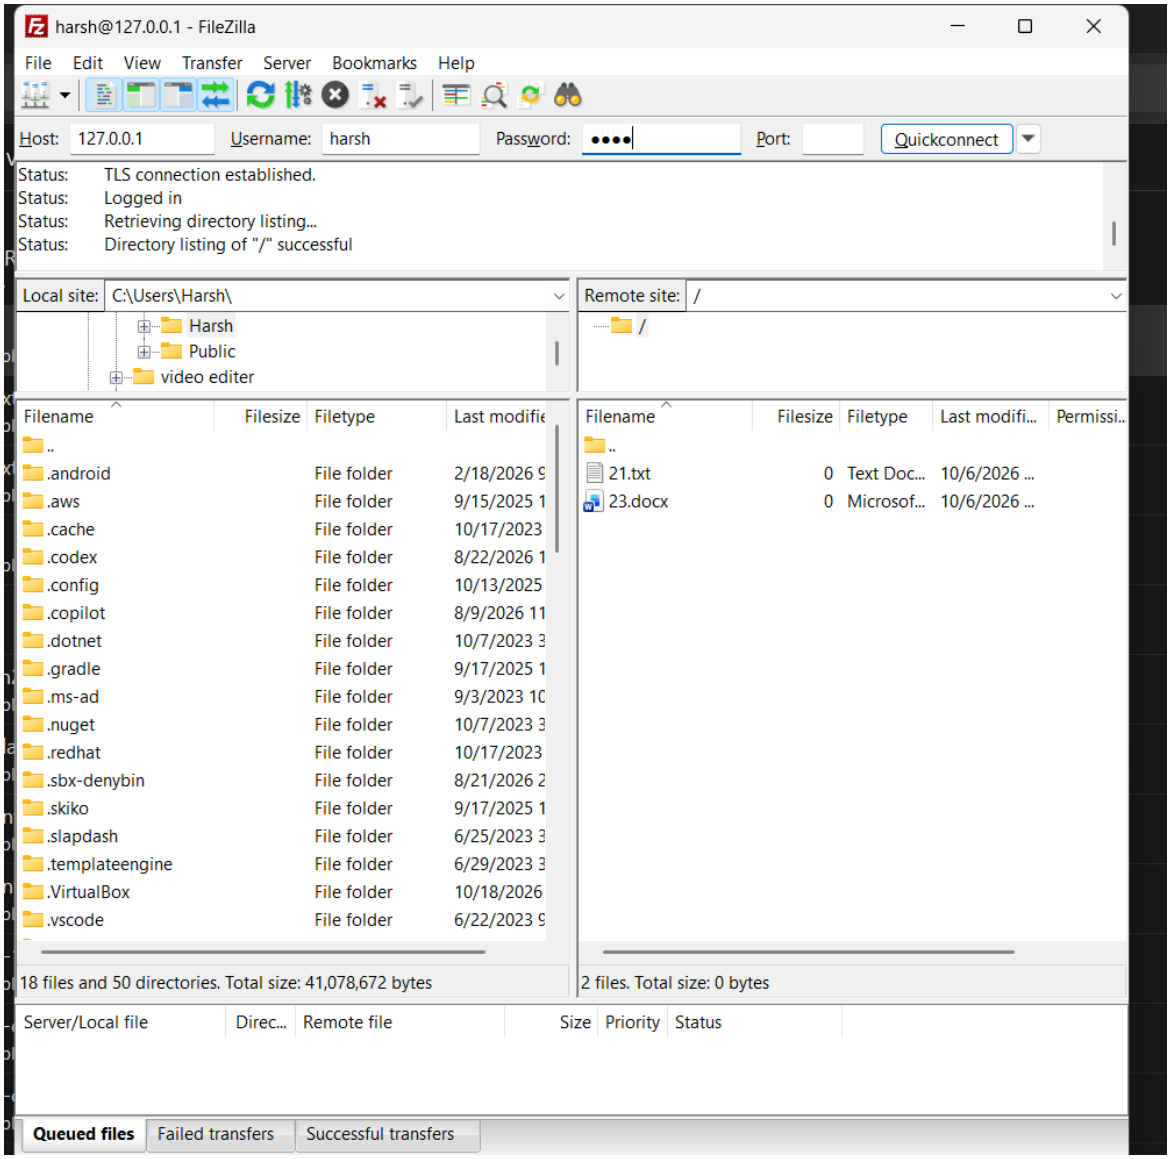

Configuration completed: FileZilla Server was installed and configured on the Windows machine.

1. User Account: Created an FTP user account with login credentials.
2. Shared Folder: Selected a folder and configured access permissions for the user.
3. FTP Access: Configured the server to allow the user to connect and access the shared folder using FTP.

Result: FileZilla Server is configured to provide file-sharing access through the created user account and shared folder.

2. Use FileZilla Client to connect to your FTP server using the credentials you created, and upload any image file from your computer to the shared folder.

FileZilla Client successfully connected to the FTP server using the configured credentials. An image file was uploaded from the local computer to the remote shared folder, demonstrating successful FTP file transfer

3.Download the uploaded file from your FTP server to a different folder on your computer using FileZilla Client, and verify the file size matches the original.

The uploaded file was downloaded from the FTP server to a different folder on the local computer using FileZilla Client. The original and downloaded file sizes were compared to verify that the file transfer was successful.

4.Research and list 3 real-world scenarios where SNMP is used in network management for apps or services you use (such as ISPs, campus WiFi, or large websites).

No.	Real-World Scenario	How SNMP Is Used
1	ISP Network Monitoring	Internet service providers use SNMP to monitor routers and switches, check bandwidth usage, and detect network failures that may affect services like YouTube or Spotify.
2	College Campus Wi-Fi	Network administrators use SNMP to monitor Wi-Fi access points, check device status, track network traffic, and identify overloaded access points.
3	Large Website Data Centers	Companies operating large websites, such as Flipkart, can use SNMP to monitor network switches, routers, interface traffic, and device health to help maintain service availability.

5. Create a table comparing FTP and HTTP across at least 5 points: port number, security, data transfer method, use cases, and authentication.

Comparison Point	FTP (File Transfer Protocol)	HTTP (Hypertext Transfer Protocol)
Port Number	**Port 21 for control; port 20 commonly used for active-mode data**	**Port 80 by default**
Security	**Standard FTP does not encrypt data; FTPS can provide encryption**	**Standard HTTP does not encrypt data; HTTPS provides encryption**
Data Transfer Method	**Transfers files using separate control and data connections**	**Transfers web resources using request-response messages**
Use Cases	**Uploading and downloading files between computers and servers**	**Accessing websites, web pages, and online applications**
Authentication	**Supports usernames and passwords; some servers allow anonymous access**	**Usually uses application-level authentication such as sessions, cookies, or tokens**

Example	**Using FileZilla to upload files to an FTP server**	**Opening Flipkart in a web browser using HTTP or HTTPS**
